### Chapter 2: Template Editing Example 15
Chapter 1: Introduction

AllFusion ERwin DM r7.0 introduced the Template Language component (TLX) as a new template/macro language. TLX is employed in a variety of places in the product where text expansion is necessary.

The Forward Engineering and Alter Script components use TLX in order to generate the necessary SQL statements. Beginning with CA ERwin DM r7.3, you can edit these Forward Engineering and Alter Script templates to provide custom SQL output.

For the rest of this document, the term "templates" refers to the Forward Engineering and Alter Script templates.

Note: Templates were present in AllFusion ERwin DM r7.0 through AllFusion ERwin DM r7.2. However, as noted in the documentation of those releases, these templates used an interim format and changes to them were unsupported. Prior versions of templates cannot be used in CA ERwin DM r7.3. Both the file format and the template syntax have changed with the production version of templates. Beginning with the r7.3 format, changes to templates are supported. The file format and template syntax will be supported in future versions of the product and changes made will be usable when the software is upgraded.

This section contains the following topics:

Documentation (see page 7)
Template Location (see page 8)
Terminology (see page 8)
Template Editing (see page 9)

Documentation

For effective template editing, you need to be familiar with CA ERwin DM's metamodel, and have a working knowledge of TLX.

The CA ERwin DM metamodel is documented in the ERwin Metamodel Reference. The syntax for TLX and the macros available are documented in the Template Language and Macro Reference. Both of these documents are located in the \Doc subdirectory where this product is installed.
Template Location

By default, the templates are installed to a subdirectory of the Application Data directory of your machine, typically \Documents and Settings\All Users\Application Data\CA\ERwin Data Modeler\7.3\Templates.

**Note:** If you do not use the *All Users* setting during product installation and enter a specific user instead, then the *All Users* subdirectory is the user name you entered.

The forward engineering template files shipped with CA ERwin DM r7.3 have an extension of .fet and are named to correspond with the DBMS to which they apply. For example, the default template file for Oracle is Oracle.fet.

**Note:** You will find other files in the Templates directory that have different extensions. These are templates for other purposes and are not covered by this document.

If you want to restore the default template files that shipped with CA ERwin DM r7.3, the install program places read-only copies of the files in the BackupFiles\Templates subdirectory where this product is installed.

Terminology

The terminology used differs slightly from that of older versions of CA ERwin DM. The following table describes the differences in the terminology:

<table>
<thead>
<tr>
<th>Term</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Template</td>
<td>A piece of TLX code. In this document, it refers specifically to templates used for the purpose of generating SQL for Forward Engineering or Alter Script. For example, the <em>Create View</em> template is used to generate a <em>CREATE VIEW</em> statement.</td>
</tr>
<tr>
<td>Template File</td>
<td>A collection of templates for a specific purpose stored externally. For example, the Oracle Template File (Oracle.fet) contains all the templates for Forward Engineering and Alter Script against an Oracle database.</td>
</tr>
<tr>
<td>Macro</td>
<td>A <em>function</em> supported by TLX that evaluates to a specific value or provides a specific control structure. For example, the <em>Date</em> macro evaluates to a string representing the current date/time.</td>
</tr>
</tbody>
</table>
Template Editing

This section provides an overview of template editing.
Opening the Template Editor

You can edit template files in any text editor that supports plain text format. However, the Template Editor in CA ERwin DM r7.3 provides several features that make editing templates easier, such as auto-expansion and macro selection.

To open the editor, click Forward Engineering Templates on the Tools menu.

This menu item is available whenever a physical or logical/physical model is active. The physical side of a logical/physical model does not need to be displayed in the workspace to edit its templates.

You can also open the editor when you click the Edit button in either the Forward Engineer Schema Generation or the Alter Script Schema Generation dialog, as shown in the following illustration:
Option Sets

Each physical or logical/physical model has a `FE_Option_Set` object associated with it that holds the option settings you select. There is a default that is created by CA ERwin DM and you can create new ones. Though several `FE_Option_Set` objects can exist in the model, only one can be designated as active at a time.

When the Template Editor expands a template, it takes into account the current settings for the model. In CA ERwin DM r7.3, options are not saved to the model immediately upon selection in the user interface. To write the settings to the model and have them available to the Template Editor, you must either save them explicitly with the `Save` or `Save As` buttons, or save them implicitly when you click the `Generate` or `Preview` buttons, as shown in the following illustration:
The Template Editor

The Template Editor is shown in the following illustration:

![Template Editor-SQLServer2005:Create Entity](image)

- Sample Context: E/1 [Entity] (Model_1)
- Create Check Constraint Usage
- Create Constraint
- Create Default
- Create Default Constraint Usage
- Create Domain
- Create Entity
- Macro Selectors: Access_DatabaseName, Access_Datatype, Allow_Alter_Datatype, AreAllOwnershipCreated, AreAllOwnershipDeleted, AreStringsEqual, ClearAllGlobalFlags, ClearGlobalFlag, ClearLocalFlag
- Expanded Text:

```sql
/* Make sure that Create Entity is executed only OnceForObject( "Create Entity" )

CREATE TABLE E_1
|
| a char(18) NOT NULL ,
| CONSTRAINT XPKE_1 PRIMARY KEY CLUSTERED (a ASC)
| go
```
The following list describes the tools and controls available in the Template Editor:

- Opens a different template file.
- Saves the template file or lets you make a copy of the file.
- Prints the selected template.
- Inserts a new template into the template file.
- Deletes a template from the template file.
- Searches for text in the template.
- Repeats your last search in the template.
- Replaces text in the template.
- Toggles auto-indenting in the template.
- Toggles sorting of macros by categories.
- Invokes the Template Editor Preferences dialog.
- Invokes the Macro Categories dialog.
- Launches the online help.
Sample Context

Allows you to select the starting object that will be used for the expansion of the template. By default, the editor attempts to select an Entity object when it is invoked. For each object listed, it shows the name of the object, its type, and a string representing its ownership chain in the model to allow objects with the same name to be distinguished from each other.

Note: Consult the Template Language and Macro Reference document to ensure you have a basic understanding of the context stack.

Since a large model might have sufficient objects to exceed Windows' limits for a combo box, only three objects of each type in the model are added to the list. If you want to see all objects in your model, select the Show All check box.

Templates

Shows all templates found in the template file. They are categorized based on their names as follows: Create, Alter, Drop, and Insert templates; Clause templates (reusable fragments employed by other templates); and Miscellaneous templates. Double-click a template to edit it. By default, when the Template Editor is invoked, it attempts to select the Create Entity template.

Macros

Shows the macros supported in TLX. By default, they are listed alphabetically. You can toggle the display to show them grouped by categories. You can create new categories and add macros to them using the Macro Categories dialog. The icon next to the macro indicates its deprecation status. You can learn about the various deprecation levels in the Template Language and Macro Reference document, and suppress the display of deprecated macros using the Template Editor Preferences dialog. Double-click a macro to insert it into the template at the current location.

Template Source

Shows the TLX code of the template. It is syntax-colored, but you can change the color choices in the Template Editor Preferences dialog.

Expanded Text

Shows the result of expanding the template against the current context object. Alternatively, it may show error information if a mistake is made in editing the template. It is syntax-colored, but you can change the color choices in the Template Editor Preferences dialog.
Chapter 2: Template Editing Example

This section provides an example of creating a template to demonstrate the mechanics of editing a template. This example creates a very simple version of a CREATE TABLE template and tests it against the EMPLOYEE table in the emovies.erwin sample model.

**Note:** This example assumes the target server of your model is SQL Server 2000. However, the process is the same for all supported target servers.

The template produced here will not cover the full syntax of a CREATE TABLE statement. Once you understand the principles here, you can examine the full templates shipped with CA ERwin DM to guide you in customizing your SQL.
Follow these steps to create the example template:

**Basic Template - Version 1**

The first pass demonstrates the steps to produce the following SQL:

```sql
create table EMPLOYEE
(
  employee_first_name varchar(20),
  employee_address varchar(20),
  employee_phone integer,
  employee_address_2 varchar(20),
  employee_number varchar(20),
  soc_sec_number integer
  hire_date datetime,
  salary integer,
  email varchar(20),
  store_number integer,
  supervisor varchar(20)
)
```

**Getting Started**

Template files are quite extensive in order to cover all of the SQL required for CA ERwin DM's processes. The easiest way to start is to make a copy of an existing template file and edit it to produce the custom SQL you want:

- Go to the C:\Documents and Settings\<user_name>\Application Data\CA\ERwin Data Modeler\7.3\Templates directory, make a copy of SqlServer.fet, and name it SqlServer2.fet. This prevents unwanted changes to the real template file.
- Start CA ERwin DM and load emovies.erwin.
- Click Forward Engineering Templates on the Tools menu to invoke the Template Editor.
- Click the Open tool and load SqlServer2.fet.

Make sure the EMPLOYEE [Entity] table is selected in the Sample Context box. If you cannot find it, turn on Show All.
Entry Point Templates

The Forward Engineering component of CA ERwin DM looks for templates with certain names to use as the starting point for a particular SQL command. For a `CREATE` statement, the name of the entry point template is `Create XXX` where `XXX` is the class name for the object type. The entry points for other types of statements follow this pattern; `DROP` statements have entry points of `Drop XXX`, `ALTER` statements have entry points of `Alter XXX`, and so on.

**Note:** Consult the *ERwin Metamodel Reference* to locate the class names for various object and property types.

The class name for a table is *Entity*, so the `Create Entity` template is edited:

- Select the `Create Entity` template (it is probably already selected) and press F2. Rename that template to `Create Entity old`.
- Select the *New Template* tool and name the new template `Create Entity`.

At this point, the Template Editor attempts to expand the new template and displays a message that an undetermined parsing error occurred - this is expected.

The Template

This version of the template uses three macros: `Property`, `ForEachOwnee`, and `ListSeparator`.

**Note:** Consult the Template Language and Macro Reference document if you are uncertain of TLX syntax, or to see full descriptions of the macros used here.

- Type the following code into the *Template Source* field of the editor:

  ```plaintext
  "create table " Property("Physical_Name")
  "\n"
  ForEachOwnee("Attribute")
  {
    ListSeparator("")
    "\n\t" Property("Physical_Name") "" Property("Physical_Data_Type")
  }
  "\n"
  ```

After a moment, the following text appears in the *Expanded Text* field:

```plaintext
create table EMPLOYEE
(
  employee_first_name varchar(20),
  employee_address varchar(20),
  employee_phone integer,
  employee_address_2 varchar(20),
  employee_number varchar(20),
```
soc_sec_number integer
hire_date datetime,
salary integer,
email varchar(20),
store_number integer,
supervisor varchar(20)
)

**Splitting SQL Scripts - Version 2**

The Forward Engineering component needs to be able to split up the various SQL statements that are generated to the script. Parsing the script during generation is too slow, so tokens are placed into the script to indicate the split points. These tokens are inserted by a macro called *FE::EndOfStatement*.

Tokens representing instructions to the Forward Engineering component are all delimited by double @ symbols (@@).

- Put your cursor in the *Template Source* field after the last line.
- Double-click the *FE::EndOfStatement* macro in the *Macros* tree.

After a moment, the following text appears in the *Expanded Text* field:

```sql
create table EMPLOYEE
(
    employee_first_name varchar(20),
    employee_address varchar(20),
    employee_phone integer,
    employee_address_2 varchar(20),
    employee_number varchar(20),
    soc_sec_number integer
    hire_date datetime,
    salary integer,
    email varchar(20),
    store_number integer,
    supervisor varchar(20)
)
)
go

/*@EOS*/

**Subsidiary Templates - Version 3**

Describes subsidiary templates and the use of the *Execute* macro.
Execute Macro

One template can delegate some of the processing to another template using the Execute macro. Another template is created called Emit FK and it is delegated to produce the foreign key constraints for the table:

- Select the New Template tool and name the new template Emit FK.
- Add the following as temporary code for the new template. This code will be replaced later in the example.
  
  "Got here"

- Double-click the Create Entity template again to go back to editing it and add the following text at the end. The use of the Equal macro causes nothing to emit if the current Key_Group is not a foreign key.

  ```
 ForEachOwnee("Key_Group")
  {
      Equal( Left( Property("Key_Group_Type"), 2 ), "IF" )
      Execute("Emit FK")
      FE::EndOfStatement
  }
  ```

After a moment, the following text appears in the Expanded Text field:

```sql
create table EMPLOYEE
(
    employee_first_name varchar(20),
    employee_address varchar(20),
    employee_phone integer,
    employee_address_2 varchar(20),
    employee_number varchar(20),
    soc_sec_number integer
    hire_date datetime,
    salary integer,
    email varchar(20),
    store_number integer,
    supervisor varchar(20)
)
); go
@@*EOS*@@
```

"Got here"

```sql
go
@@*EOS*@@
```

"Got here"

```sql
go
@@*EOS*@@
```

"Got here"

```sql
go
@@*EOS*@@
```
Controlling the Context Stack

The `Got here` statement can now be replaced in the `Emit FK` template with code to emit an `ALTER` statement that adds the foreign key. Since such a statement requires information from the `Entity` object, the `Attribute` objects owned by it, the `Relationship` object, and the `Key_Group_Member` objects, the template code will have to control the context stack to make sure that properties are read from the correct object.

**Note:** This is not the most efficient way to produce the intended output, but it accomplishes the task without complicating the example with a lot of new macros.

- Double-click on the `Emit FK` template to edit it.
- Replace the existing text with the following code:

```
"alter table " PushOwner Property("Physical_Name") Pop
"inn add foreign key ("
ForEachOwnee("Key_Group_Member")
{
  ListSeparator("," Property("Physical_Name")
}
") references "
PushReference("Relationship_Ref")
PushReference("Parent_Entity_Ref")
Property("Physical_Name")
Pop
Pop
" ("
ForEachMigratingColumn
{
  ListSeparator("," Property("Physical_Name")
}
")
""
PushReference("Relationship_Ref")
"n\on delete "
UpperCase( Property("Relationship_Parent_Delete_Rule") )
Pop
```
- Ignore the parsing error that appears in the `Expanded Text` field (because the template was not entered from the correct starting point) and double-click the `Create Entity` template to get the entry point template to evaluate.
After a moment, the following text appears in the *Expanded Text* field:

```sql
create table EMPLOYEE
(
  employee_first_name varchar(20),
  employee_address varchar(20),
  employee_phone integer,
  employee_address_2 varchar(20),
  employee_number varchar(20),
  soc_sec_number integer
  hire_date datetime,
  salary integer,
  email varchar(20),
  store_number integer,
  supervisor varchar(20)
)

go
@@"EOS"@@

alter table EMPLOYEE
add foreign key (store_number) references STORE (store_number)
on delete NO ACTION
go
@@"EOS"@@

alter table EMPLOYEE
add foreign key (supervisor) references EMPLOYEE (employee_number)
on delete NO ACTION
go
@@"EOS"@@
```
**Sorting the Output - Version 4**

One of the foreign keys in the EMPLOYEE table is self-referential. However, the other is not; it references the STORE table. If the order of processing the Entity objects results in the STORE table emitting after the EMPLOYEE table, the ALTER statement creating the foreign key will fail.

To avoid this, tokens can be emitted that instruct the Forward Engineering component to sort types of statements into groups. These groups are called buckets. Any statement placed in Bucket #1 is emitted before any statement placed in Bucket #2, which is before any statement in Bucket #3, and so on. There can be an arbitrary number of buckets. The macro \texttt{FE::Bucket} inserts the bucket tokens.

- Insert the following code as the first line of the Create Entity template:
  
  \texttt{FE::Bucket("10")}

- Insert the following code right after the first occurrence of the \texttt{FE::EndOfStatement} macro:
  
  \texttt{FE::Bucket("20")}

After a moment, the following text appears in the Expanded Text field:

```sql
@@*B=10*@@
create table EMPLOYEE
   (employee_first_name varchar(20),
    employee_address varchar(20),
    employee_phone integer,
    employee_address_2 varchar(20),
    employee_number varchar(20),
    soc_sec_number integer
    hire_date datetime,
    salary integer,
    email varchar(20),
    store_number integer,
    supervisor varchar(20))
go
@@*EOS*@@

@@*B=20*@@
alter table EMPLOYEE
   add foreign key (store_number) references STORE (store_number)
on delete NO ACTION
  go
@@*EOS*@@
```
When the templates are executed against the entire model, all of the `CREATE TABLE` statements (Bucket #10) will emit before any of the `ALTER` statements (Bucket #20).
